EDUCATE. EMPOWER. SECURE THE FUTURE.

COURSE 1.1 / COMPANION WORKBOOK

Windows Server

DC01 and DC02

Promote Primary & Secondary Domain Controller

A practical companion for promoting two Active Directory domain controllers on a network segment of their own, checking the result, and recording evidence.

MATERIALS EDITION 0.7 / COURSE 1.1

What is Active Directory?

The shared directory behind domain identities.

A directory for people and computers

Active Directory Domain Services (AD DS) is the Windows Server directory service. It stores objects such as user accounts, computer accounts, and groups, together with their attributes. Administrators use this shared directory to organize identities and manage access consistently.

The domain and the controller

A domain is a logical collection of directory objects, named here sbd.test. A domain controller (DC) is a server running AD DS that stores and serves that directory. DC01 and DC02 are two servers serving the same domain. A forest contains one or more domains; this build starts with one.

Identity, permissions, and policy

Authentication checks who is signing in. Authorization determines what that identity may access. Signing in successfully does not grant access to every resource: the destination service still applies its permissions. Groups make it practical to assign access to roles instead of managing every person separately.

Organization and consistent settings

Organizational units (OUs) organize objects and support delegated administration and Group Policy. Group Policy applies centrally managed settings to users and computers. A global catalog helps find directory objects across a forest; both controllers in this course provide that role.

REMEMBER AD DS stores the directory, and every domain controller serves it. Authentication proves who someone is; authorization decides what they may reach.

THINK IT THROUGH Explain the difference between the sbd.test domain and the SBD-DC01 server.

Where do the controllers live?

On a segment of their own, behind a core that denies by default.

A segment reserved for controllers

SBD-DC01 and SBD-DC02 sit on VLAN 10 (10.0.10.0/24), a segment that holds domain controllers and nothing else. Workstations, member servers, security tools, and administrators sit on segments of their own. The core joins the segments, and its VLAN 10 address, 10.0.10.1, is the controllers' default gateway.

Deny by default, allow by exception

The core denies every session between segments unless a documented rule permits it, and logs what it denies. Members reach the controllers only for name resolution (course 1.2) and the services in "What crosses the network?". Traffic between the two controllers stays inside VLAN 10, so the core never routes it.

Only Tier 0 manages a controller

From other segments, Remote Desktop, PowerShell remoting, and AD Web Services reach a controller only from AdminJumpBox01, the Tier 0 host on VLAN 60 that course 1.8 builds; until then, use the VM console. Members still reach SMB and RPC, which can carry administration too, so Tier 0 accounts never sign in to them.

Two layers, and no internet

Windows Defender Firewall stays on in every profile and blocks what no rule allows, so an unopened port stays closed even if a core rule is wrong. Keep Remote Desktop off. The directory rules accept any address, and the remoting and AD Web Services rules do too until course 1.8 limits them to the Tier 0 host, so the core decides who reaches those ports. No segment routes to the internet; approved media is the only way in.

REMEMBER A controller's segment is part of its security: VLAN 10 for controllers only, default deny at the core, management only from Tier 0, and the host firewall on in every profile.

THINK IT THROUGH A workstation on VLAN 80 can open Remote Desktop to SBD-DC01. Which two layers failed, and where would you look first?

SEE IT INSIDE THE NETWORK

VLAN 10: the domain controllers' segment, with its boundary, both controllers and their addresses, and the controls that apply.

Why use two domain controllers?

Keep the directory available when one server is unavailable.

Remove the single-server dependency

With one DC, its outage removes the only live directory service point. With two healthy, reachable controllers, clients can use a surviving DC for supported operations. This also lets you patch or restart one server while the other continues serving requests. Reconnection may take time; uninterrupted service is not guaranteed.

Both controllers do useful work

Both writable DCs can process normal directory changes and authentication requests. Replication shares directory changes between them. “Primary” and “secondary” describe the order you promote them, not a primary server and an idle spare. Certain operations still depend on a single FSMO role holder, so role placement and recovery need their own plan.

Make the redundancy real

Microsoft recommends at least two virtualized DCs per domain on different virtualization hosts. Two VMs on one host share that host as a failure point. Consider shared storage, power, and network dependencies too.

Availability still needs recovery

Replication can spread an accidental deletion or harmful change to both servers. Keep protected backups and test recovery separately. Two is a starting point for this design, not a universal capacity target: additional sites, users, and recovery needs may require more controllers.

REMEMBER Before relying on DC02, verify replication, review shared dependencies, and confirm both controllers pass their health checks.

THINK IT THROUGH If both controllers run on the same physical host, which outage would still stop both services?

SEE IT INSIDE THE NETWORK

DC01 is down, step 3: with SBD-DC01 offline, the workstation authenticates with SBD-DC02 instead, so sign-in continues.

What crosses the network?

The ports a domain member needs to reach its domain controllers.

Domain members sit on other segments, so each conversation in this table crosses the core, which allows it only because a rule says so. Inside the Network shows each one crossing the core switch. The table starts after name resolution, which course 1.2 covers.

PURPOSE	PORT	WHAT IT CARRIES
Authentication	TCP/UDP 88	Kerberos tickets
Password change	TCP/UDP 464	Kerberos password changes and resets
Directory	TCP/UDP 389 · TCP 636	LDAP and LDAPS; UDP 389 carries the domain controller locator ping
Global catalog	TCP 3268 · 3269	Forest-wide searches; 3269 uses TLS
Group Policy and SYSVOL	TCP 445	SMB reads of policies and scripts from domain controller shares
RPC services	TCP 135 · 49152–65535	Endpoint mapper, then the dynamic range for NetLogon, LSA, and SAM
Time	UDP 123	W32Time; members follow the domain time hierarchy
Administration	TCP 3389 · 5985–5986 · 9389	Remote Desktop, PowerShell remoting, and AD Web Services, only from the Tier 0 administration host

REMEMBER Allowing Kerberos isn't enough. Applying Group Policy and reading SYSVOL also need LDAP, SMB, and RPC. In the Inside the Network design, rules F02, F03, and F09 permit this profile for domain members, with LDAP signing and channel binding required, and rule A01 limits administration to the Tier 0 host. Name resolution has its own rule (F01), and so does credentialed scanning (F15), which arrives with course 1.17, coming soon; everything else is denied.

THINK IT THROUGH A workstation gets Kerberos tickets, but Group Policy never applies. Which ports would you check first?

SEE IT INSIDE THE NETWORK

Sign in, step 4: after it authenticates, the workstation reads directory information and Group Policy from SBD-DC01.

01 / PREPARE

Plan your build

Build two new domain controllers on their own segment of an isolated network. The interactive guide contains the detailed steps, verification commands, and chapter evidence fields.

What you will learn

- Promote DC01, then add DC02 to the same domain, on a segment of their own.
- Inspect service state, replication health, and both controllers' roles.
- Connect configuration choices to security reasoning and evidence.

Before you begin

Use two new Windows Server (Desktop Experience) VMs on VLAN 10, the segment reserved for domain controllers, with console access and approved installation media. Record your starting OS builds. Keep this exercise isolated; sample domain values must match your own environment plan.

Sample configuration

SETTING	SAMPLE VALUE
Domain and NetBIOS	sbd.test / SBD
First controller	SBD-DC01 / 10.0.10.10/24
Second controller	SBD-DC02 / 10.0.10.11/24
Segment and gateway	VLAN 10 (10.0.10.0/24) / 10.0.10.1, the core
DC02 DNS server	10.0.10.10 (SBD-DC01)
Network and time	Isolated, no internet / record the internal time source

CM-2 BASELINE Record the intended values and the observed starting configuration. Keep the baseline aligned with changes to the build.

© 2026 Secure By Design Team LLC.

Build DC01

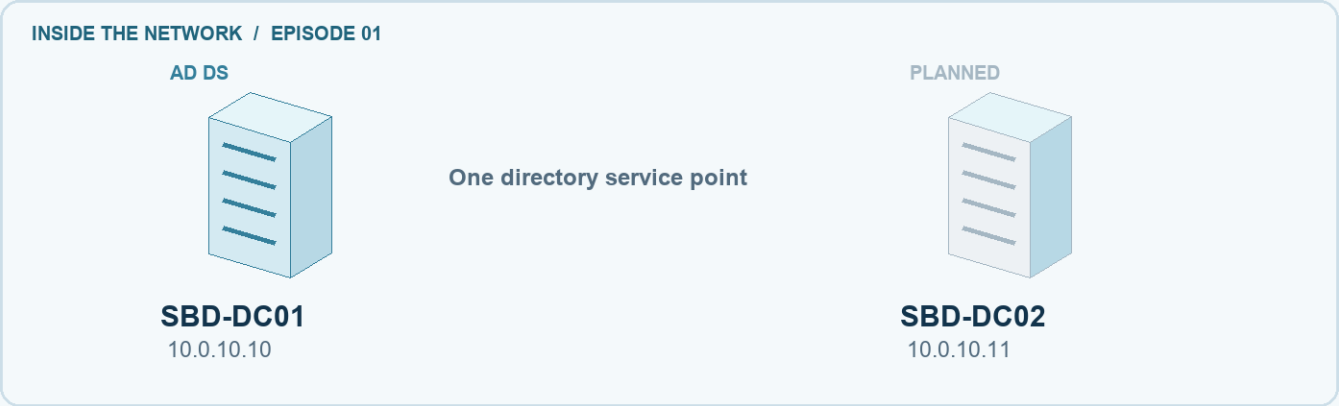

WHY THIS MATTERS Create the sample forest and its first domain controller.

Follow the build

1. On DC01, add the Active Directory Domain Services role and its management tools through Server Manager.

2. Promote the server using Add a new forest and sbd.test. Leave DNS server selected; the DNS delegation warning is expected, and course 1.2 explains both. The first controller is always a global catalog. Choose the highest functional levels the wizard offers and a unique DSRM password.

3. Review the SBD name, paths, and prerequisites. Read any warnings, resolve blocking errors, install, and restart.

NETWORK STATE DC01 configured; DC02 planned.

Check your result

```
Get-ADDomain | Select-Object DNSRoot, NetBIOSName
Get-Service NTDS,Netlogon
Get-SmbShare -Name SYSVOL,NETLOGON
```

Expect the planned domain and running services, with both shares present. Investigate missing results before adding DC02.

CM-6 SETTINGS Record the promotion choices and why they fit the environment. Keep passwords out of evidence.

COMMON MISTAKE Role installation alone does not complete domain-controller promotion.

© 2026 Secure By Design Team LLC.

Add DC02

WHY THIS MATTERS Add another writable controller to the same domain.

Follow the build

1. Point DC02 at DC01 (10.0.10.10) for DNS and leave it that way; course 1.2 explains the DNS design. Check network reachability and clock alignment.

2. Install AD DS, then choose Add a domain controller to an existing domain. Use sbd.test and authorized domain credentials. Leave DNS server and global catalog selected.

3. Review site, replication source, DSRM password, and prerequisites. Install and restart.

NETWORK STATE Two controllers with a replication relationship.

Check your result

```
Get-ADDomainController -Filter *
repadmin /replsummary
repadmin /showrepl SBD-DC02
```

Expect both controllers and successful recent replication. Record any unresolved errors.

CP-9 RECOVERY A second controller supports availability. Backups and tested recovery remain separate work.

COMMON MISTAKE Choose the existing-domain option. A new forest would create a separate directory.

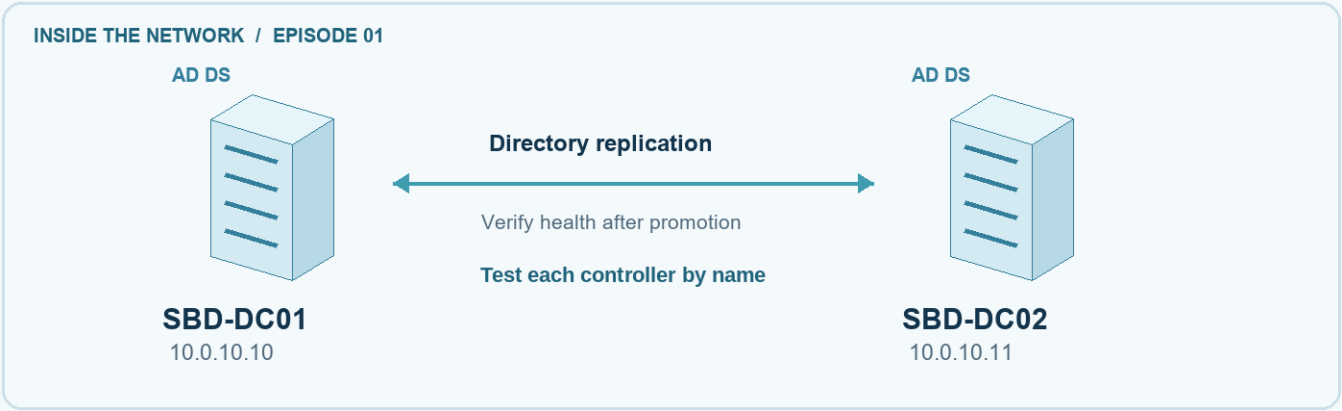

© 2026 Secure By Design Team LLC.

Verify the domain

WHY THIS MATTERS Ask each controller for an observable result.

Follow the build

1. On either controller, in elevated PowerShell, run DCDiag against SBD-DC01, then SBD-DC02.
2. Check replication both ways: the summary, then each controller's inbound partners.
3. Check the global catalogs, the five roles on SBD-DC01, and SYSVOL and NETLOGON on DC02.
4. Confirm the domain profile and the effective firewall policy on each controller.

NETWORK STATE **Check each controller and confirm replication both ways.**

Check your result

```
dcdiag /s:SBD-DC01
dcdiag /s:SBD-DC02
repadmin /replsummary
repadmin /showrepl *
Get-ADDomainController -Filter * | Select-Object HostName, IsGlobalCatalog
netdom query fsmo
Get-SmbShare -Name SYSVOL,NETLOGON -CimSession SBD-DC02
Get-NetConnectionProfile | Select-Object InterfaceAlias, NetworkCategory
Get-NetFirewallProfile -PolicyStore ActiveStore |
  Select-Object Name, Enabled, DefaultInboundAction
```

Expect each DCDiag test to pass or have a recorded cause, replication both ways, both shares on both controllers, and every firewall profile on and blocking. A command that ran is not a pass.

IA-2 SIGN-IN Healthy, replicating controllers are a precondition for domain sign-in. These checks do not establish all authentication requirements.

COMMON MISTAKE A successful ping does not show replication, SYSVOL, or sign-in health.

05 / EVIDENCE

Keep a useful build record

Use My evidence in the interactive guide to save chapter notes, confirm your checks, and answer each question. Export your record before moving to another browser or device.

Your evidence summary

Record the final domain and controllers, their segment and gateway, actual role holders, dated test output, and unresolved issues. Reference files stored in your own environment; do not record credentials.

RMF CONNECTION Implementation records what was configured. Assessment examines evidence. Monitoring revisits conclusions as the system changes.

Completion checklist

☐ I recorded actual settings and the reasons for them.

☐ I checked both controllers' health, replication, and host firewall.

☐ I kept dated evidence and described failures or limits.

☐ I listed recovery, hardening, and client checks still to do.

What did you observe

Evidence file names, collection time, key results, and the next action

GO FURTHER Explain why replication cannot recover every unwanted change. Identify a change that would trigger a new replication or health check.

© 2026 Secure By Design Team LLC.

Continue the learning path

The workbook and interactive companion use the same five chapters. The recorded walkthrough is coming soon. Read the current sources before adapting the sample to another environment. Next in the path: course 1.2, Configure DNS.
